48 B Weight-Mixing Implementation

```
PyTorch-Style Forward Pass of Weight-Mixing Mixture-of-LoRA Layer
expert_alphas = router(...) # (b, num_experts)
expert_weight_A = (expert_alphas[..., None, None] * self.
    expert_weight_A[None]).sum(
    dim=1
   # (b, r, in_features)
expert_weight_B = (expert_alphas[..., None, None] * self.
    expert_weight_B[None]).sum(
    dim=1
  # (b, out_features, r)
output = torch.einsum(
    "bi,bri->br", x, expert_weight_A
  # (b, in\_features) @ (b, r, in\_features) -> (b, r)
output = torch.einsum(
    "br,bor->bo", output, expert_weight_B
  # (b, r) @ (b, out_features, r) -> (b, out_features)
output = self.dropout(output) # (b, out_features)
output = F.linear(x, w0, b0) + output # w0x + BAx + b0
```

50 C Style Consistency Metric Visualization

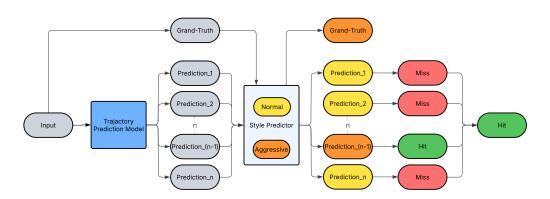

Figure 7: **Style Consistency Metric.** Given a driving scenario ("Input"), the black-box trajectory predictor generates n candidate futures (Prediction₁,..., Prediction_n). A learned style predictor then assigns each candidate—and the true future ("Ground-Truth")—to one of two clusters (e.g. "Normal" vs. "Aggressive"). If at least one of the n predicted trajectories shares the same style label as the ground-truth, the sample is marked a Hit; otherwise it is a Hit is a Hit is outcome directly measures whether the model's multi-modal outputs Hit cover the driver's actual style, beyond conventional displacement errors.

Style Consistency Metric 451

- To explicitly measure a model's ability to cover the correct driving style, as shown in Figure 7, we 452
- 453 propose the Style Miss Rate a style consistency metric based on kinematic clustering following the
- clustering methodology introduced in [38], and a hit/miss criterion: 454
- **Extract kinematic static:** For each trajectory τ , compute a feature vector 455

$$\phi(\tau) = \left[\max_{t} |a(t)|, \ Var(a), \ Var(v), \ \gamma \right]^{\mathsf{T}} \in \mathbb{R}^d, \tag{8}$$

- where a is acceleration (with $\max_{t} |a(t)|$ denoting the peak absolute acceleration over the trajectory,
- i.e. the highest instantaneous acceleration magnitude), v is speed, and

$$\gamma = \frac{\operatorname{Var}(j(t))}{\mathbb{E}[j(t)]}$$

- is the jerk-variance ratio as defined in [22] 458
- **Learn style clusters:** Fit a Gaussian Mixture Model (GMM) with k=2 on the set of all ground-truth kinematic embeddings in the evaluation set $\{\phi(\tau_n^*)\}_{n=1}^N$, yielding a cluster assignment function 459
- 460

$$C(\phi) \in \{\text{"normal"}, \text{"aggressive"}\}.$$
 (9)

- Normal and aggressive are assigned based on the mean speed of each cluster. A cluster with higher 461
- mean speed will be assigned as aggressive. 462
- **Assign styles to predictions:** For each sample n, let $\{\hat{\tau}_{n,i}\}_{i=1}^6$ be the six predicted trajectories. 463
- 464

$$s_n^* = C(\phi(\tau_n^*)), \quad s_{n,i} = C(\phi(\hat{\tau}_{n,i})). \tag{10}$$

Define hit/miss: A hit occurs if at least one predicted style matches the ground-truth style: 465

$$\operatorname{Hit}_n = \{ \exists i : s_{n,i} = s_n^* \}, \quad \operatorname{Miss}_n = 1 - Hit_n.$$
 (11)

Style Miss Rate: The overall metric is

$$SMR = \frac{1}{N} \sum_{n=1}^{N} Miss_n.$$
 (12)

- By construction, the SMR goes beyond pure spatial accuracy: it measures whether the model 467
- "covers" the driver's true style among its multi-modal outputs. A style-agnostic predictor may achieve 468
- low ADE/FDE by clustering its modes around average behavior, but will incur a high miss rate 469
- on aggressive samples. In contrast, a style-aware model—conditioned on inferred driving-style 470
- embeddings—should include at least one candidate trajectory whose kinematics align with the true 471
- style, yielding a lower SMR. 472

E Style Miss Rate Evaluation on Ablation Variants

To further assess how each component of our mixture-of-experts framework contributes to style coverage, we compute the Style Miss Rate (SMR) on the same ablation variants presented in Table 14. That is, for each model variant—removing reconstruction, KL loss, entropy regularization, etc.—we evaluate how often none of its multi-modal predictions match the true driving style cluster. The resulting SMR values are reported in Table 5. This analysis shows that the ablations which most degrade traditional error metrics (e.g. reconstruction and KL removal) also incur the largest increases in SMR, indicating a direct link between component contributions and the model's ability to cover the driver's style.

Table 5: Style Miss Rate (SMR) for each ablation variant.

Ours	SMR↓
+LinearRouter	0.2246
+Full Finetuning	0.2033
-Social Forces	0.2229
-Context Features	0.2236
-KL Loss	0.2267
-Reconstruction	0.2263
-Expert Entropy Loss	0.2260

F How does the model reason? Taking a look at the saliency maps.

To gain insight into which input features the model attends when forecasting agent trajectories, we compute saliency maps by measuring the sensitivity of the most likely predicted trajectory with respect to each input feature. Formally, let $X = \{A_{\rm in}, M_{\rm in}\}$ denote the concatenation of historical object trajectories $A_{\rm in}$ and map polylines $M_{\rm in}$. If \hat{p}_{τ} is the probability of trajectory τ , then let $\hat{\tau}^* = \arg\max_{\tau} \hat{p}_{\tau}$ be the most likely predicted trajectory after a forward pass from a model. Then, we compute the gradient

$$\nabla_X \hat{\tau}^* = \frac{\partial \hat{\tau}^*}{\partial X}$$

via back-propagation, and form the saliency map

$$S(X) = \log(\|\nabla_X \hat{\tau}^*\|_2 + 1).$$

We use logarithmic scaling above to better display nuances in smaller gradient magnitudes. For visualizing this saliency map, we render the map polylines and the agents' historical trajectories colored using S(X). Warmer colors highlight map segments or agent trajectories that the model deems more important for predicting future trajectories. Likewise, lighter colors highlight areas of less importance. Each agent vehicle is also colored on the same scale based on the maximum saliency value of its historical trajectory. We generate this visualization for both the MTR+Actions baseline model and the Ours+MoV model.

490 G Additional Visualizations for Relative Kinematics by Expert

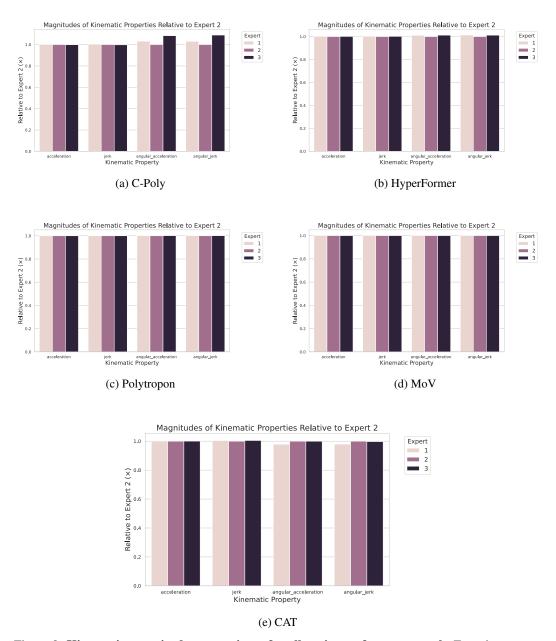

Figure 8: **Kinematic magnitude comparisons for all variants of our approach.** Experiments run with seed 0 are plotted.
